From the Wikipedia:

A pattern (...) is a type of theme of recurring events or objects, sometimes referred to as elements of a set. These elements repeat in a predictable manner. (...) Pattern matching is the act of checking for the presence of the constituents of a pattern, whereas the detecting for underlying patterns is referred to as pattern recognition.

Normally, queries involving *maps* and *filters* extract information (eg. by counting) ignoring the patterns which layout such information.

< □ > < 同 > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

- Suppose we want to check whether a particular data element *d* occurs in a list *l*.
- There are several ways to provide an answer to such a query.
- The easiest is to evaluate d ∈ l the answer is a Boolean (*True* or *False*), with maximal loss of information.
- Another is to count the number of occurrences of d in I: check d I = (length ∘ filter (≡ d)) I

There is more information now — should d occur in l, we know how often.

• Still we have lost the information of where in the list such occurrences take place: all at the front? scattered? all at the tail?

Pattern recognition Indexing Word inversion Searching Abstraction Sampling Epilogue Finding indices in sequences

The following function tells which positions in a list are occupied with data satisfying a particular condition p:

findIndices
$$p \ l = [i \mid (x, i) \leftarrow zip \ l \ [0 \dots], p \ x]$$

To see how *findIndices* is more informative than *filter*, run the following query inspecting "rondo word" "ARBRCRBRA"

```
findIndices (\equiv 'R') "ARBRCRBRA" = [1, 3, 5, 7]
```

and compare with

filter (\equiv 'R') "ARBRCRBRA" = "RRRR"

Pattern recognition Indexing Word inversion Searching Abstraction Sampling Epilogue How findIndices works

1st step — zipping: *zip* "ARBRCRBRA" [0..] yields

[('A',0),('R',1),('B',2),('R',3),('C',4),('R',5),('B',6),('R',7),('A',5),('B',6),('R',7),('A',5),('A',5),('B',6),('A',7),('A',5),('A',

▲ロト ▲帰 ト ▲ヨト ▲ヨト - ヨ - の々ぐ

2nd step — filtering via $x \equiv R'$ yields [('R', 1), ('R', 3), ('R', 5), ('R', 7)]

3rd step — selecting right component of pairs, yielding $\label{eq:component} \begin{bmatrix} 1,3,5,7 \end{bmatrix}$

Pattern recognition Indexing Word inversion Searching Abstraction Sampling Epilogue Word (sequence) inversion

Note how easy it is to record the list of positions occupied by all elements in a list:

invert
$$I = nub [(x, findIndices (\equiv x) I) | x \leftarrow I]$$

For instance,

```
invert "ARBRCRBRA" = [('A', [0,8]), ('R', [1,3,5,7]), ('B', [2,6]), ('C', [4])]
```

clearly tells the role of A (begin = end), refrain R, intermediate episode B and middle episode C.

Let us now generalize isPrefixOf so that it checks whether a particular pattern p occurs in a list l at position i:

match $p \mid i = p$ 'isPrefixOf' (drop $i \mid l$)

For instance, not only isPrefixOf "Mendel" "Mendelssohn" = True holds, but also

< □ > < 同 > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

match "ssohn" "Mendelssohn" 6 = True

Clearly,

isPrefixOf p I = match p I 0

Las but not least, we may think of a function which records in which positions in a list a particular pattern occurs:

patternIndices $p \mid =$ [($i, i + length \mid p - 1$) | (x, i) $\leftarrow zip \mid [0..], match \mid p \mid i$]

Consider, for instance,

Epilogue

Searching for patterns

Clearly, this piano sonata fragment (right hand only) is captured by $tune = ntimes \ cell1 \ 3 + (ntimes \ cell2 \ 4) + cell3$

where

So,

patternIndices cell1 tune = [(0,5), (6,11), (12,17)]patternIndices cell2 tune = [(18,23), (24,29), (30,35), (36,41)]patternIndices cell3 tune = [(42,47)]

as expected.

However,

- One has the feeling that there is **only one** cell in this fragment which repeats at different degrees of the scale. Howe can we capture this?
- We need an **abstraction** mechanism which should be able to abstract from each cell the pattern of intervals involved.
- For this we need to model the notion of **interval** between two degrees in a diatonic scale.

Prior to all this, let us investigate how some other *music abstraction* functions can be encoded in Haskell.

More subtle filtering functionality

Think of the function *copy* which copies its input faithfully to the output, that is, *copy* x = x. Surely, this function has the following properties,

▲ロト ▲帰 ト ▲ヨト ▲ヨト - ヨ - の々ぐ

copy
$$[] = []$$

copy $[x] = [x]$
copy $(s + r) = (copy s) + (copy r)$

from which we easily calculate

$$copy [] = []$$

 $copy [x] = [x]$
 $copy (x : r) = x : (copy r)$

as earlier on.

Function*copy* can be easily converted into one that removes duplicates (*ndcopy*) by adding a filter at each stage:

$$\begin{array}{l} ndcopy \ [] = [] \\ ndcopy \ [x] = [x] \\ ndcopy \ (x:r) = x: (filter \ (\not\equiv x) \ (ndcopy \ r)) \end{array}$$

NB: *ndcopy* is nothing but the standard function *nub* to which we have resorted earlier on.

▲ロト ▲帰 ト ▲ヨト ▲ヨト - ヨ - の々ぐ

- Between these two extremes (copying everything or removing all duplicates) there is the intermediate operation which removes only consecutive duplicates.
- To see the difference, compare

ndcopy "Mendelssohn" = "Mendlsoh"

(all duplicates go out) with

ncdcopy "Mendelssohn" = "Mendelsohn"

(only "s" in "ss" gets filtered.

• How do we encode *ncdcopy*?

Abstraction: removing local repeats

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

Removing **all** duplicates:

$$\begin{array}{l} ndcopy \ [] = [] \\ ndcopy \ [x] = [x] \\ ndcopy \ (x:r) = x: (filter \ (\not\equiv x) \ (ndcopy \ r)) \end{array}$$

Removing consecutive duplicates only:

$$ncdcopy [] = []$$

$$ncdcopy [x] = [x]$$

$$ncdcopy (x : y : r)$$

$$| x \equiv y = ncdcopy (x : r)$$

$$| x \not\equiv y = x : ncdcopy (y : r)$$

Recall that music notes are pairs (n, d) of note pitch with duration. Abstracting from repeated notes is trickier because we want to keep durations of the notes we are going to remove:

▲ロト ▲帰 ト ▲ヨト ▲ヨト - ヨ - の々ぐ

$$nrep [] = [] nrep [a] = [a] nrep ((n, d) : (n', d') : l) | n \equiv n' = nrep ((n, d + d') : l) | n \not\equiv n' = (n, d) : nrep ((n', d') : l)$$

Consider, for instance, the beginning of the *Presto* of Beethoven's String Quartet op.74:

Now the same once *nrep*'ed:

(Note the binary meter flavour of the first bars, which could be thought of as being $\frac{6}{8}$.)

Pattern recognition Indexing Word inversion Searching Abstraction Sampling Epilogue Removing locally repeated notes

In Haskell, here is (the beginning) of the original tune:

$$\begin{split} &tune = [("c", 1 \% 8), ("c", 1 \% 8), ("c", 1 \% 8), ("C", 3 \% 8), ("e", 1 \% 8), ("e", 1 \% 8), ("e", 1 \% 8), ("e", 3 \% 8), ("g", 1 \% 8), ("g", 1 \% 8), ("g", 1 \% 8), ("c", 1 \% 4), ("e'", 1 \% 4), ("c", 1 \% 4), ("=B", 1 \% 4), ...] \end{split}$$

Now the effect of *nrep*:

$$\begin{array}{l} \textit{nrep tune} = [("c", 3 \% 8), ("C", 3 \% 8), ("e", 3 \% 8), ("E", 3 \% 8), ("g", 3 \% 8), ("c", 1 \% 4), ("e'", 1 \% 4), ("c", 1 \% 4), ("s", 1 \% 4), ("c", 1 \% 8), \ldots] \end{array}$$

▲ロト ▲帰 ト ▲ヨト ▲ヨト - ヨ - の々ぐ

Sampling for musical analysis

In this case, a list of durations is the additional input (sampler) which tells at which points in time notes are to be selected, while keeping the durations specified by the sampler:

$$\begin{aligned} sample :: (Ord d, Num d) \Rightarrow [d] \rightarrow [(n, d)] \rightarrow [(n, d)] \\ sample []_{-} = [] \\ sample _{-} [] = [] \\ sample (y:r) ((a, x):t) \\ | y < 0 \land x + y \equiv 0 = sample r t \\ | y < 0 \land x + y > 0 = sample r ((a, x + y):t) \\ | y < 0 \land x + y < 0 = sample ((x + y):r) t \\ | y > 0 \land y < x = (a, y): sample r ((a, x - y):t) \\ | y > 0 \land y > x = (a, y): sample ((x - y):r) t \\ | y > 0 \land y \equiv x = (a, y): sample r t \end{aligned}$$

Sampling for musical analysis

Two different samples of op.74iii,

 \square

where the latter loses more information, keeping only the tonal thread.

Exercise 1: Write in Haskell the sampler lists which yield the above two samples of op.74iii main theme.

Epilogue

Sampling keeps what's essential

Sampling enables the music analyst to capture a view, or projection, of the target tune. For instance, given source

Sonata K331i

W.A. Mozart (1756-1791)

the following sample

removes rhythmic detail while keeping the main rhythmic structure, that given by rhythmic pattern 4, that is, $\frac{2}{8}, \frac{1}{8}$.

Another sample, this time over $\frac{3}{16}$,

(which could be regarded as having meter $\frac{12}{16}$) keeps the melodic structure.

- When used together with the other combinators described in this series of slides, sampling offers support for musical analysis by **removing detail** (eg. passing notes, short rhythmic patterns) and providing a **view** (analysis) of the musical text.
- Melodic pattern identification calls for a **metric structure** in musical pitch enabling us to calculate the **derivative** of a melodic line, ie., the sequence of intervals involved.
- From melodic derivatives we can (re)build tunes again, by the converse operation of **integration**.

• Such is the purpose of the next set of slides in this series.
