Outline				

- 2 Data Refinement
- Implementation

# 4 Example

Introduction	Data Refinement	Implementation	Example	Conclusion
●○	000	00000	0000	O
Motivation				

Two-level Type-level transformation of a data format coupled with the corresponding value-level transformation of data instances.

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 の�?

Introduction	Data Refinement	Implementation	Example	Conclusion
●0	000	00000	0000	O
Motivation				

- Two-level Type-level transformation of a data format coupled with the corresponding value-level transformation of data instances.
- Type-safe Type-checking guarantees that the data migration functions are well-formed with respect to the type-level transformation.

Introduction	Data Refinement	Implementation	Example	Conclusion
●0	000	00000	0000	O
Motivation				

- Two-level Type-level transformation of a data format coupled with the corresponding value-level transformation of data instances.
- Type-safe Type-checking guarantees that the data migration functions are well-formed with respect to the type-level transformation.

User-driven XML schema evolution coupled with document migration.

Automated Data mappings for storing XML in relational databases.

Introduction	Data Refinement	Implementation	Example	Conclusion
⊙●	000	00000	0000	O
Ingredients				

- Concrete data models are abstracted as Haskell data types.
- Type-level transformations are data refinements.
- Strategic programming to compose flexible rewrite systems.

  - combinators for traversal construction.

## Combinators

```
(>>>) :: Rule -> Rule -> Rule
(|||) :: Rule -> Rule -> Rule
nop :: Rule
many :: Rule -> Rule
once :: Rule -> Rule
```

Introduction	Data Refinement	Implementation	Example	Conclusion
		00000		
Represent	tation of Types			

#### The Type of Types

```
data Type a where
    Int :: Type Int
    String :: Type String
    One :: Type ()
    List :: Type a -> Type [a]
    Map :: Type a -> Type b -> Type (Map a b)
    Either :: Type a -> Type b -> Type (Either a b)
    Prod :: Type a -> Type b -> Type (a,b)
    Tag :: String -> Type a -> Type a
```

00	000	00000	0000	O
Type-Cha	nging Rewrite	Rules		

How to combine strategic programming with type-changing rules?

Masquerade Changes as Views

```
data Rep a b = Rep {to :: a \rightarrow b, from :: b \rightarrow a}
```

```
data View a where
    View :: Rep a b -> Type b -> View (Type a)
```

The Type of Rules

type Rule = forall a . Type a -> Maybe (View (Type a))

## Refine Lists by Maps

▲ロト ▲帰ト ▲ヨト ▲ヨト 三日 - の々ぐ

### Rule Implementation

listmap :: Rule
listmap (List a) = Just (View rep (Map Int a))
where rep = Rep {to = seq2index, from = list}
listmap \_ = Nothing

## Rule Implementation

listmap :: Rule
listmap (List a) = Just (View rep (Map Int a))
where rep = Rep {to = seq2index, from = list}
listmap \_ = Nothing

### Rewrite System for Hierarchical-to-Relational Mapping

flatten :: Rule
flatten = many (once (listmap ||| mapprodmap ||| ...))

00	000	0000	0000	0		
Unleashing the Migration Functions						

- The target type is existentially quantified in a view.
- Since its not known statically we can use a staged approach:
  - Apply the intended transformation to compute it dynamically and get its string representation using showType.
  - Incorporate that string in the source and unleash the migration functions.

```
forth :: View (Type a) -> Type b -> a -> Maybe b
back :: View (Type a) -> Type b -> b -> Maybe a
```

```
data Equal a b where Eq :: Equal a a
teq :: Type a -> Type b -> Maybe (Equal a b)
```

Introduction of a Music Album Format

# Evolution of a Music Album Format

## Concrete XML Schema

```
<element name="Album" type="AlbumType"/>
<complexType name="AlbumType">
   <attribute name="AlbumType">
   <attribute name="ASIN" type="string"/>
   <attribute name="Title" type="string"/>
   <attribute name="Artist" type="string"/>
   <attribute name="Format">><simpleType base="string">
   <attribute name="Format">><simpleType base="string">
   <attribute name="Format">><simpleType base="string">>
   <attribute name="Format">><simpleType base="string">>
   <attribute name="Format">><simpleType base="string">>
   <attribute name="Format"><simpleType base="string">>
   <attribute name="Format"><simpleType base="string">>
   <attribute name="Format"><<attribute name="CD"/></attribute</a>
```

({0 := ((("B000002UB2","Abbey Road"),"Beatles"),0),
    1 := ((("B000002HCO","Debut"),"Bjork"),1)},
    {(0,0) := "Come Together",
    (0,1) := "Something",
    ...})
```

Introduction	Data Refinement	Implementation	Example	Conclusion
00	000	00000	0000	•
Conclusion				
Conclusion				

- Conclusions:
  - Type-safe formalization of two-level data transformations.
  - Haskell's type system, namely GADTs, allows a direct and elegant implementation.
  - Allows flexible rewrite systems but termination and confluence is not guaranteed.

• Restricted to single-recursive data types.

Introduction	Data Refinement	Implementation	Example	Conclusion
00	000	00000	0000	•
Conclusion				

- Conclusions:
  - Type-safe formalization of two-level data transformations.
  - Haskell's type system, namely GADTs, allows a direct and elegant implementation.
  - Allows flexible rewrite systems but termination and confluence is not guaranteed.
  - Restricted to single-recursive data types.
- Current status:
  - Coupled transformation of data processing programs, such as queries expressed in a point-free notation.

• Front-ends for XML and SQL database schemas.
